# Let's Start!

# Finite State Automata

- Finite Automata(FA) is the simplest machine to recognize patterns.
- The finite automata or finite state machine is machine which have five elements or tuple( $Q, \Sigma, q, F, \delta$ )
- It has a set of states and rules for moving from one state to another but it depends upon the applied input symbol. Basically it is an abstract model of digital computer.
- There are two types of finite state machines (FSMs): deterministic finite state machines, often called deterministic finite automata, and non-deterministic finite state machines, often called non-deterministic finite automata.

# Question 1

- A real number is written as string of digits containing a decimal point.
- There must be atleast one digit before and after the decimal point.
- A real data item written in scientific notation consists of a sign followed by a real number, followed by the letter E, another +/- sign and an integer
- For ex. .9 and 9. are invalid and 0.9, 9.0, +1.2, -22.34, 22.3E+23, -2.3E2 are all valid.

# Solution:

# Ex. 1

Input = 9.

## Ex. 2

Input = 22.3E+23

# Question 2

- We have a house, with one door, 2 buttons and 3 lights. At the default state the lights are all turned off.
- When you enter the house, you can press one of the 2 push buttons you have, P1 or P2. When you press any of those buttons, the l1 light turns on.
- As we know that we are talking about the real life scenario over here.
- This Finite State Machine is slightly more complex, because this time we have multiple routes depending on the input given by user.

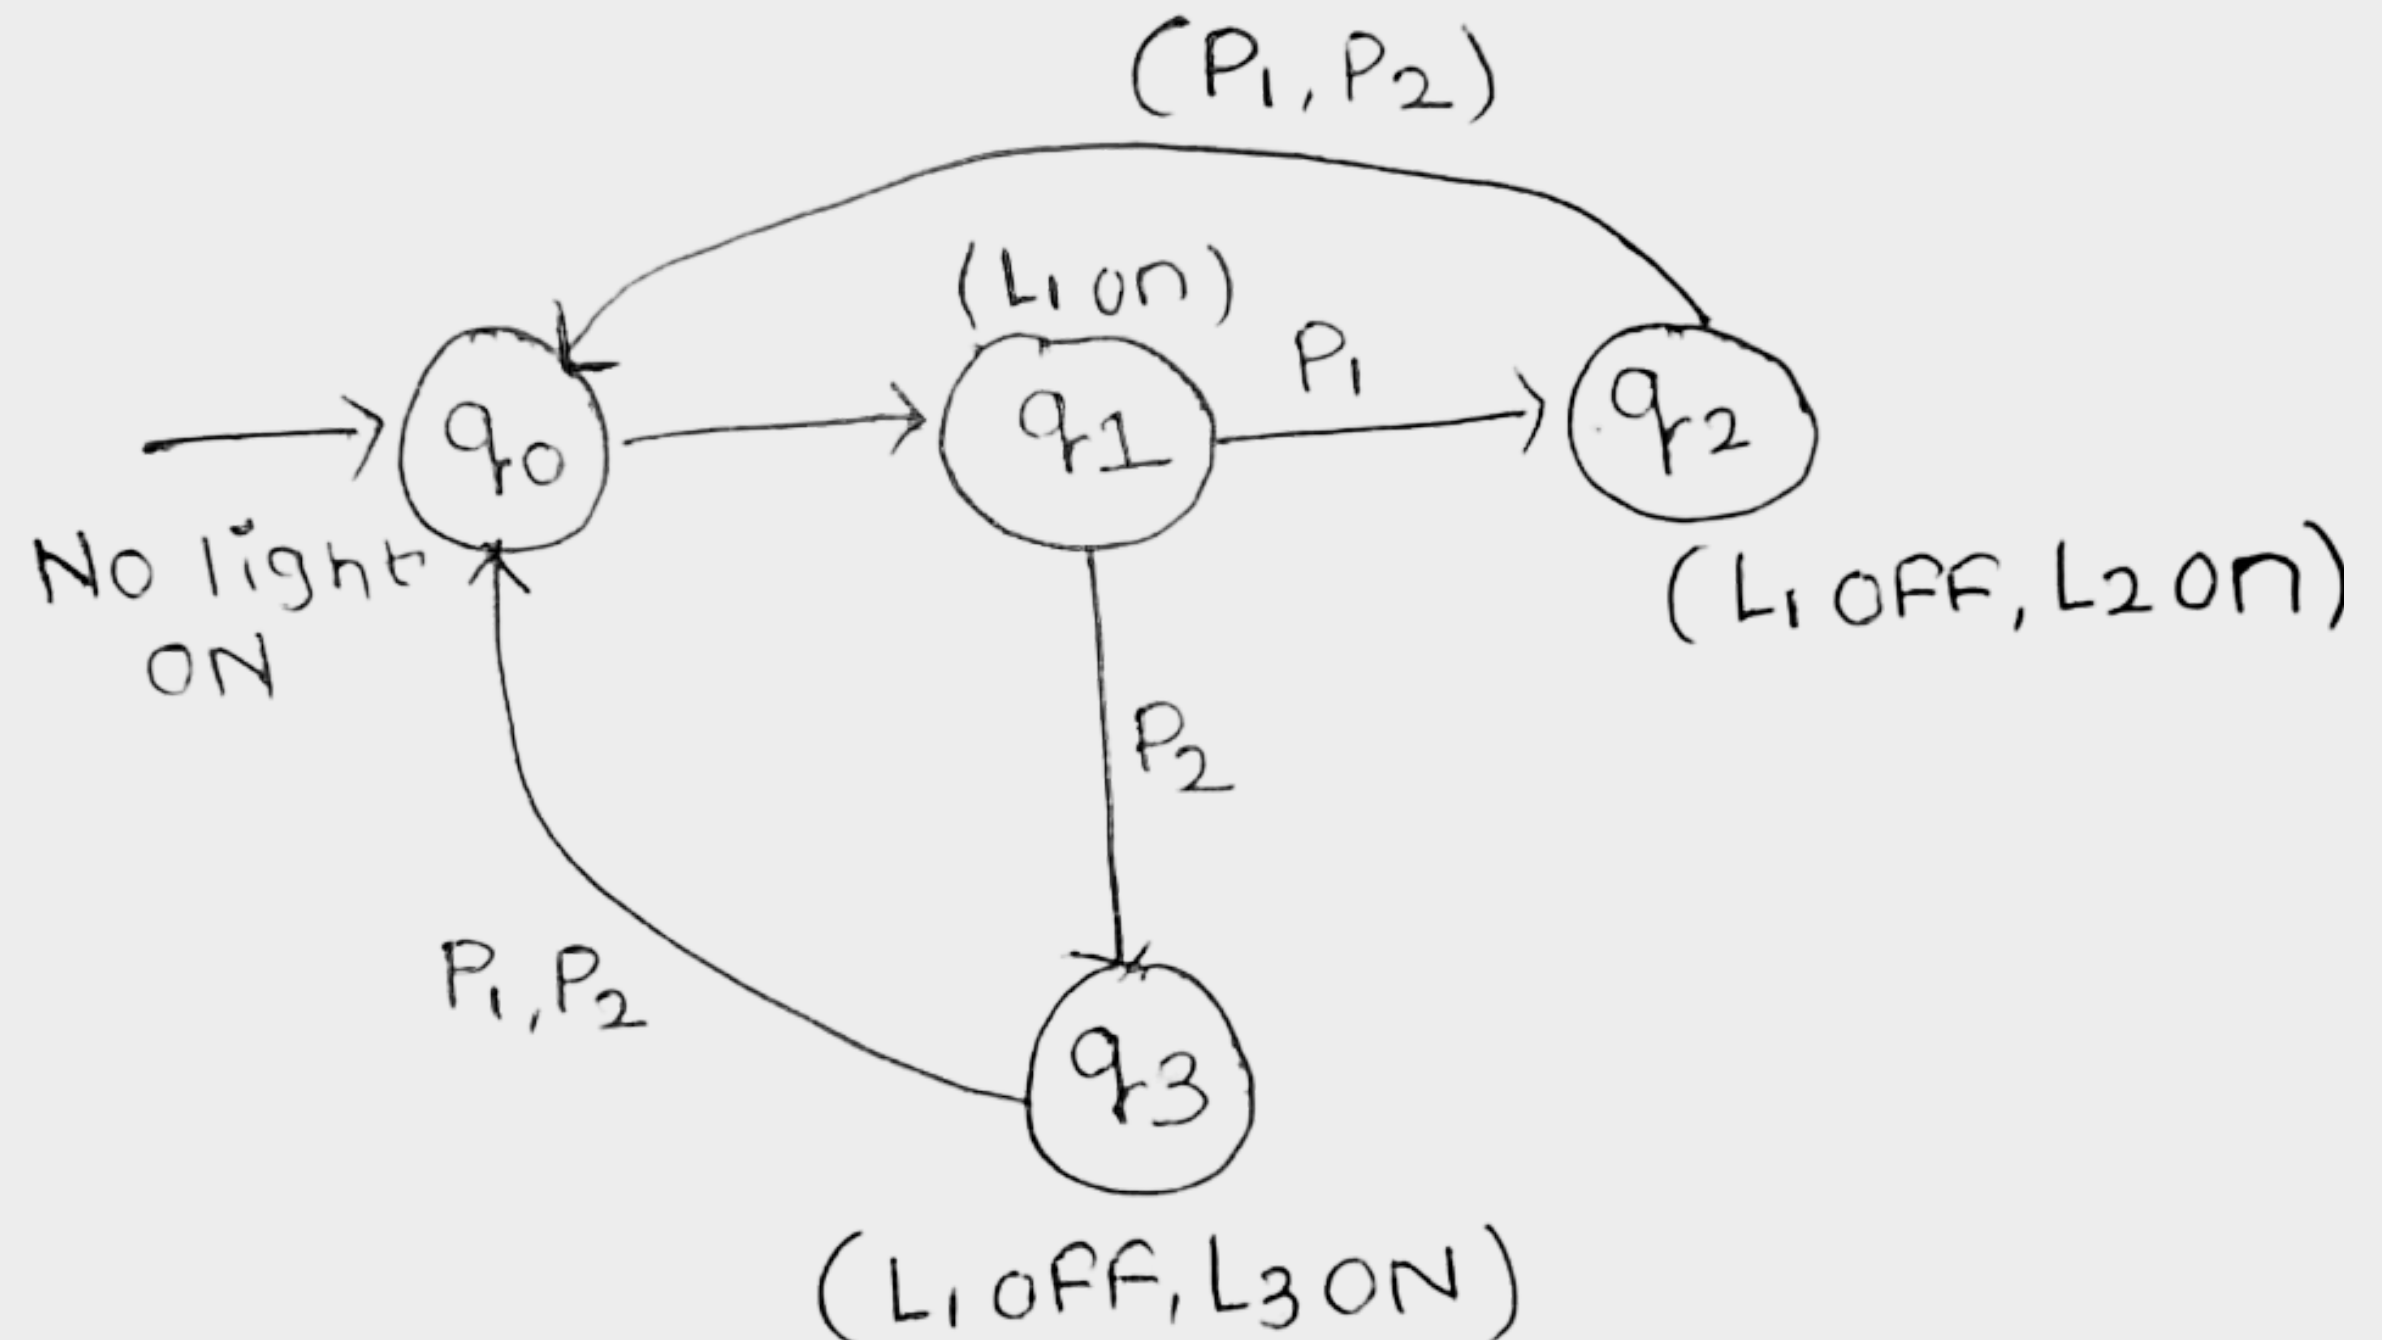

# Solution

So, we are having 4 states :-

1. No lights on
2. L1 on
3. L2 on
4. L3 on

we are having 2 inputs as well :-

1. P1
2. P2

# Question 3

Develop, Implement and Execute a program using YACC tool to recognize all strings ending with 'bbb' preceded by n a's using the grammar  $a^n bbb$  (note: input n value)
